JET ENERGY SCALE SETTING
WITH « $\gamma + Jet$ » EVENTS AT LHC ENERGIES.
DETAILED STUDY
OF THE BACKGROUND SUPPRESSION

Presented at the «XV ISHEPP»,
September 25–29, 2000, Dubna, Russia

2000

1. INTRODUCTION

This paper continues our previous publications [1–4], where possibilities of jet energy scale setting and calibration of the hadron calorimeter at LHC energies by using “ $\gamma + Jet$ ” process have been studied.

This article is devoted to the study of the background events suppression and to demonstration of the efficiency of the cuts introduced by us in paper [1] for this purpose.

2. ILLUSTRATION OF NEW CUTS EFFICIENCY

To estimate the background for the signal events, we have done the simulation¹ with a mixture of all QCD and SM subprocesses existing in PYTHIA with large cross sections, namely: ISUB=1, 2, 11–20, 28–31, 53, 68, which can lead to a big background for our main “signal” subprocesses (ISUB=14 and 29 in PYTHIA)²:

$$qg \rightarrow q + \gamma \quad (1a)$$

$$q\bar{q} \rightarrow g + \gamma \quad (1b)$$

Three generations (each of $50 \cdot 10^6$ events) with different values of minimal P_t of hard process \hat{p}_\perp^{min} ³ have been done: the first one is with $\hat{p}_\perp^{min} = 40$ GeV/c, while the second and the third – with $\hat{p}_\perp^{min} = 100$ and 200 GeV/c, respectively.

We have selected “ γ -candidate + 1 Jet” events with $P_t^{jet} > 30$ GeV/c containing one γ -candidate to be identified by the detector as an isolated photon with $P_t^\gamma \geq 40$ (100 and 200) GeV/c for the generation with $\hat{p}_\perp^{min} \geq 40$ (100 and 200) GeV/c, respectively. One needs to stress that here and below, speaking about the γ -candidate, we imply in reality a signal that may be registered in the 3 by 3 ECAL crystal cell window with the highest P_t γ/e in the center. All these photon-candidates were supposed to satisfy the isolation criteria 1–4 of Section 3.2 from paper [1] with $P_{tCUT}^{isol} = 2$ GeV/c and $\epsilon_{CUT}^\gamma = 5\%$. No special cuts were imposed on $\Delta\phi$, P_t^{out} and P_t^{clust} (the values of P_t^{clust} are automatically limited from the top since we select “ γ -candidate + 1 jet” events with $P_t^{Jet} > 30$ GeV/c).

The corresponding distributions for the physical observables, introduced in Sections 3.1 and 3.2 from [1], are shown separately for the signal “ γ - dir” and the background events in Figs. 1, 3, 5 and in scatter plots 2, 4, 6. First columns in these figures, denoted by “ γ - dir”, show the distributions in the signal events, i.e. in the events corresponding to the processes (1a) and (1b), having direct photons with $P_t^{\gamma-dir} \geq 40$ GeV/c. The second columns, denoted as “ γ - brems”, correspond to the events in which the photons were emitted from quarks (i.e. bremsstrahlung photons) and have passed under the imposed cuts. The distributions in the third column were built basing on the events containing “ γ -mes” photons, i.e. those photons that originate from multiphoton decays of mesons (π^0 , η , ω , K_S^0) and have also passed under the imposed cuts.

Firstly we see that in the case of $P_t^\gamma \geq 200$ GeV/c (see Fig. 5) practically all “signal events” have $\Delta\phi < 15^\circ$, and in the case $P_t^\gamma \geq 100$ GeV/c (see Fig. 3) most of them are also

¹PYTHIA 5.7 version with default CTEQ2L parametrisation of structure functions is used here.

²A contribution of another possible NLO channel $gg \rightarrow g\gamma$ (ISUB=115 in PYTHIA) was found to be still negligible even at LHC energies.

³CKIN(3) parameter in PYTHIA.

within $\Delta\phi < 15^\circ$. It is seen from Fig. 1 that at lower values $P_t^\gamma \geq 40 \text{ GeV}/c$ there is still a big number (about 70%) of the signal events belonging to the interval of $\Delta\phi < 15^\circ$. From here

we conclude that the upper cut $\Delta\phi < 15^\circ$ chosen in (26) of [1] is reasonable and indeed discards a lot of background events in all P_t^γ -intervals.

From the second “ γ -brem” columns of Figs. 1, 3 and 5 one can also see that P_t^{clust} spectra of the events with bremsstrahlung photons look quite different from the analogous P_t^{clust} distributions of the signal “ γ -dir” photons. The latter distributions have most of the events in the region of small P_t^{clust} values.

Since the bremsstrahlung (“ γ -brem”) photons give the most sizable background, the found difference of the spectra prompts an idea of using a cut from the top on the value of P_t^{clust} to reduce “ γ -brem” background which dominates at large P_t^{clust} values.

The analogous difference of P_t^{out} spectra of signal “ γ -dir” events (which also concentrate at low P_t^{out} values) from those of the background “ γ -brem” and “ γ -mes” events, with longer tails at high P_t^{out} enables us to impose an upper cut on the P_t^{out} value.

Now from the scatter plots in Figs. 2, 4 and 6 as well as from Figs. 1, 3 and 5 we can conclude that the usage of cuts (rather soft here, but their further restriction will be discussed below):

on $\Delta\phi$:

$$\begin{aligned} \Delta\phi < 15^\circ, & \quad \text{for } P_t^\gamma \geq 40 \text{ GeV}/c; \\ \Delta\phi < 10^\circ, & \quad \text{for } P_t^\gamma \geq 100 \text{ GeV}/c; \\ \Delta\phi < 5^\circ, & \quad \text{for } P_t^\gamma \geq 200 \text{ GeV}/c, \end{aligned}$$

on P_t^{clust} :

$$\begin{aligned} P_{tCUT}^{clust} &= 15 \text{ GeV}/c, & \text{for } P_t^\gamma \geq 40 \text{ GeV}/c \text{ and } P_t^\gamma \geq 100 \text{ GeV}/c; \\ P_{tCUT}^{clust} &= 20 \text{ GeV}/c, & \text{for } P_t^\gamma \geq 200 \text{ GeV}/c, \end{aligned}$$

on P_t^{out} :

$$\begin{aligned} P_{tCUT}^{out} &= 10 \text{ GeV}/c, & \text{for } P_t^\gamma \geq 40 \text{ GeV}/c; \\ P_{tCUT}^{out} &= 15 \text{ GeV}/c, & \text{for } P_t^\gamma \geq 100 \text{ GeV}/c \text{ and } P_t^\gamma \geq 200 \text{ GeV}/c \end{aligned}$$

would allow to keep the main part of the signal “ γ -dir” events and to reduce noticeably the contribution from the background “ γ -brem” and “ γ -mes” events.

So, these figures evidently demonstrate how new physical variables P_t^{clust} and P_t^{out} , introduced in Sections 3.1 and 3.2 of paper [1], can be useful for separation of “ γ + Jet ” events with direct photons from the background ones (as the latter, in principle, are not supposed to have good balanced P_t^γ and P_t^{Jet}).

3. DETAILED STUDY OF BACKGROUND SUPPRESSION.

The study of this Section is based on the same sample of “signal + background” events ($50 \cdot 10^6$ for each interval of minimal P_t of the hard process: $\hat{p}_\perp^{min} = 40, 100, 200 \text{ GeV}/c$; see the beginning of Section 2) generated under the conditions described in the previous section and partially analyzed there. To demonstrate the way we have come to the final results, we

Table 1: List of the applied cuts used in Tables 2 – 5

0. No cuts;	
1. a) $P_t^\gamma \geq 40 \text{ GeV}/c$, b) $ \eta^\gamma \leq 2.61$, c) $P_t^{jet} \geq 30 \text{ GeV}/c$, d) $P_t^{hadr} < 5 \text{ GeV}/c^*$;	
2. $\epsilon^\gamma \leq 15\%$;	12. $P_t^{clust} < 20 \text{ GeV}/c$;
3. $P_t^\gamma \geq \hat{p}_\perp^{min}$;	13. $P_t^{clust} < 15 \text{ GeV}/c$;
4. $P_t^{sum} < 1 \text{ GeV}/c^{**}$;	14. $P_t^{clust} < 10 \text{ GeV}/c$;
5. $\epsilon^\gamma \leq 5\%$	15. $P_t^{out} < 20 \text{ GeV}/c$;
6. $P_t^{isol} \leq 2 \text{ GeV}/c$;	16. $P_t^{out} < 15 \text{ GeV}/c$;
7. $N_{jet} \leq 3$;	17. $P_t^{out} < P_{tCUT}^{out}$
8. $N_{jet} \leq 2$;	($P_{tCUT}^{out} = 10 \text{ GeV}/c$ for $\hat{p}_\perp^{min} = 100, 200 \text{ GeV}/c$
9. $N_{jet} = 1$;	and $P_{tCUT}^{out} = 5 \text{ GeV}/c$ for $\hat{p}_\perp^{min} = 40 \text{ GeV}/c$).
10. $\Delta\phi < 15^\circ$;	18. $\epsilon^{jet} \leq 5\%$;
11. $P_t^{miss} \leq 10 \text{ GeV}/c$;	19. $\epsilon^{jet} \leq 2\%$.

* P_t of a hadron in the 5x5 ECAL cell window, containing γ^{dir} candidate in the center.

** scalar sum of P_t in the 5x5 ECAL cell window in the region out of a smaller 3x3 window, containing γ .

shall apply the following cuts on the observable physical variables one after another according to the list presented below. The influence of these cuts on the S/B ratio is demonstrated in the following Tables 2–8. The numbers in the left-hand column (“Cut”≡“Selection”) of Table 2, that corresponds to $P_t^\gamma \geq 100 \text{ GeV}/c$, coincide with the numbers of cuts listed below, where for abbreviation reasons we shall denote the direct photon by “ γ ” as well as its candidate.

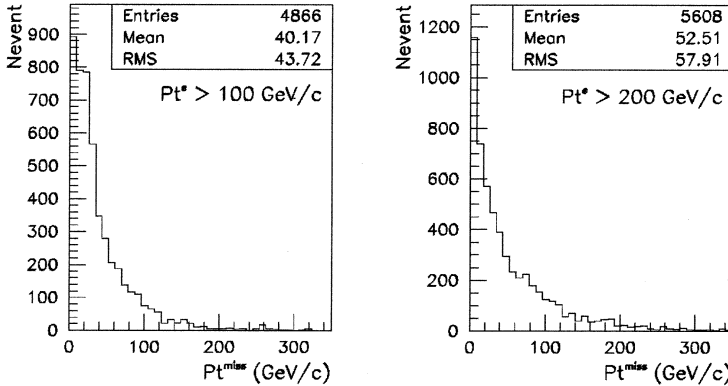

Fig. 7: Distribution of events over P_t^{miss} in events with energetic e^\pm 's – direct photon candidates for the cases $P_t^e \geq 100 \text{ GeV}/c$ and $P_t^e \geq 200 \text{ GeV}/c$ (here are used events satisfying cuts 1–3 of Table 1).

From the first line of Table 2 we see that without imposing any cut, the number of the background events exceeds the number of the signal events, caused by (1a) and (1b) processes, by 5 orders. The relative isolation cut 2 ($\epsilon^\gamma \leq 15\%$) makes the S/B ratio equal to 0.28. The cut 3 ($P_t^\gamma \geq \hat{p}_\perp^{min}$) improves the S/B ratio to 0.68. The relative isolation cut 5 and then the absolute isolation cut 6 make the S/B ratio to be equal to 1.50 and 1.93,

respectively. The requirement of only one jet presence in the event (point 9) results in the value $S/B = 5.96$. The ratio S/B is increased by the cut $\Delta\phi < 15^\circ$ up to the value 6.54 (point 10) and at the same time the number of signal events is decreased only by 5%. This is in agreement with the phenomenon of the concentration of events in the small $\Delta\phi$ angle at large P_t^γ values already mentioned in paper [2].

We have used the P_{tCUT}^{miss} cut in paper [1] to reduce value of P_t^{jet} uncertainty due to possible presence of neutrino contribution to a jet. Here it is applied against the processes based (at the parton level) on the $qg \rightarrow q' + W^\pm$ and $q\bar{q}' \rightarrow g + W^\pm$ subprocesses with the subsequent decay $W^\pm \rightarrow e^\pm \nu$ and having for this reason a substantial P_t^{miss} value. The distributions over P_t^{miss} for two P_t^e values are presented above. In the last column (e^\pm) of Table 2 it is shown how the P_{tCUT}^{miss} cut effects the number of these events (point 11).

The reduction of P_{tCUT}^{clust} value to 10 GeV/c (point 14) results in significant improvement of S/B ratio up to 17.64. Further reduction of P_{tCUT}^{out} value to 10 GeV/c (point 17) improves S/B to 22.67. The jet isolation requirement $e^{jet} < 2\%$ (point 19), finally, gives $S/B = 31.05$.

Table 2: Values of significance and efficiencies for $\hat{p}_\perp^{min}=100$ GeV/c

* The background is considered here with no account of contribution from the “ e^\pm events”

The summary of Table 2 is presented in the middle section ($\hat{p}_\perp^{min} = 100$ GeV/c) of Table 3 where in the second column (“Cuts”) line “Preselected” corresponds to the 1-st cut of the Table 2 presented above. Line “After cuts” corresponds to line 17 and line “+jet isolation” — to the complementary line 19.

In Table 3 the numbers in column “ $\gamma - direct$ ” correspond, respectively, to the numbers of the signal events in column S of Table 2 in lines 1, 17 and 19 while the numbers in the 4-th column “ $\gamma - brem$ ” correspond to the number of events with the photons radiated from quarks participating in the hard interactions (their P_t^{clust} and P_t^{out} distributions were presented in the central columns of Figs. 1–6 of Section 2). The columns from 5-th to 8-th of Table 3 illustrate the numbers of the events with the photons “ $\gamma - mes$ ”, originated from $\pi^0 -$, $\eta -$, $\omega -$, $K_S^0 -$ meson decays (their distributions were shown in the right-hand columns of the same Figs. 1–6. The total number of the background events without an account of events with electrons (see last column), i.e. a sum over columns 4–8, for the same line of Table 3 is presented, correspondingly, in the column B of Table 2.

Table 3: Number of signal and background events remained after cuts (I)

\hat{p}_\perp^{min} (GeV/c)	Cuts	γ direct	γ brem	photons from the mesons				e^\pm
				π^0	η	ω	K_S^0	
40	Preselected	7795	12951	104919	41845	10984	15058	4204
	After cuts	516	48	41	10	0	5	0
	+ jet isol.	122	7	5	1	0	1	0
100	Preselected	19359	90022	658981	247644	69210	85568	47061
	After cuts	1179	34	13	4	1	0	22
	+ jet isol.	683	15	5	2	0	0	13

	After cuts	1074	18	2	4	0	0	10
	+ jet isol.	916	16	1	4	0	0	8

Table 4: Efficiencies and significance values in events without jet isolation cut (I)

\hat{p}_\perp^{min} (GeV/c)	S	B	$Eff_S(\%)$	$Eff_B(\%)$	S/B	S/\sqrt{B}
40	516	104	6.62 ± 0.30	0.056 ± 0.005	5.0	50.6
100	1179	52	6.09 ± 0.18	0.005 ± 0.001	22.7	163.5
200	1074	24	3.29 ± 0.10	0.002 ± 0.000	44.8	219.2

Table 5: Efficiencies and significance values in events with jet isolation cut (I)

\hat{p}_\perp^{min} (GeV/c)	S	B	$Eff_S(\%)$	$Eff_B(\%)$	S/B	S/\sqrt{B}
40	122	14	1.57 ± 0.14	0.008 ± 0.002	8.7	32.6
100	683	22	3.53 ± 0.14	0.002 ± 0.000	31.1	145.6
200	916	21	2.81 ± 0.09	0.001 ± 0.000	43.6	199.9

The other lines of Table 3 for cases $\hat{p}_\perp^{min} = 40$ and 200 GeV/c have the meaning analogous to those described above for $\hat{p}_\perp^{min} = 100$ GeV/c.

The last column of Table 3 shows the number of the events with electrons which with non-zero probability can be detected as direct photon. The following columns of Table 2 define efficiencies $Eff_{S(B)}$ (and their errors) as a ratio of the number of signal (background) events that passed under some cut (1–19) to the number of the preselected events (1-st cut of

this table). The last column of Table 2 contains the values of significances (without account of events with electrons). The numbers in Tables 4 and 5 accumulate in compact form the information of Table 3. So, for the middle line ($\hat{p}_\perp^{min} = 100 \text{ GeV}/c$ case) columns S and B contain the numbers of the signal and background events taken at the level of line 17 (for Table 4) and line 19 for Table 2). The column $Eff_{S(B)}$ includes the values of efficiencies⁴ and their errors.

Table 6: Signal vs. background (II)

\hat{p}_\perp^{min} (GeV/c)	Cuts	γ direct	γ brem	photons from the mesons				e^\pm

Table 8: Values of efficiencies and significance with jet isolation cut (II)

$\hat{p}_\perp^{min}(\text{GeV}/c)$	S	B	$Eff_S(\%)$	$Eff_B(\%)$	S/B	S/\sqrt{B}
40	109	9	1.40 ± 0.13	0.005 ± 0.002	12.1	36.3
100	615	20	3.18 ± 0.13	0.003 ± 0.000	30.8	137.5
200	825	16	2.53 ± 0.09	0.002 ± 0.000	51.6	206.3

From Table 4 it is seen that ratio S/B grows while the P_t^γ value growing from 5.0 at $P_t^\gamma \geq 40 \text{ GeV}/c$ to 44.8 at $P_t^\gamma \geq 200 \text{ GeV}/c$. The jet isolation requirement (Table 5) sufficiently improves the situation at low P_t . In that case S/B changes up to 8.7 at $P_t^\gamma \geq 40 \text{ GeV}/c$ (and up to 31.1 at $P_t^\gamma \geq 100 \text{ GeV}/c$). Here it is necessary to remind about the conclusion on the tendency of the selected events to contain an isolated jet: their number grows while the P_t^γ value increasing. Practically all jets with $P_t^{jet} \geq 200 \text{ GeV}/c$ are isolated (compare two last lines of Table 3)⁵.

⁴taken as a ratio of the number of signal S (background B) events, that passed under cut 17 or 19, to the number of the preselected events in the point 1 of Table 2.

⁵see also Fig. 10 for $P_t^\gamma \geq 300 \text{ GeV}/c$ from [1]

Up to now we have not used the rejection factors, that were found basing on the detector capability to discriminate the background. Let us discuss how the values in Tables 2–5 can be changed by taking into account the real behavior of processes in the detectors.

We have performed a detailed study (based on CMSIM GEANT simulation using 5000 generated decays of each source meson from Table 3) of difference between ECAL profiles of photon showers from mesons and those from direct photons for $P_t^\gamma = 40 \div 100 \text{ GeV}/c$. It has shown that the suppression factor of η -, ω -, K_S^0 -mesons larger than 0.90 can be achieved with a selection efficiency of single photons taken to be 90%. As for the photons from π^0 decays, the analogous estimations of the rejection efficiencies were done for the Endcap

In Tables 3 and 6 we have not presented separately the background due to γ /jet misidentification because as it was shown in [9], γ and jet can be discriminated with a high precision and, secondly, as it was mentioned in Section 2 of this paper (see also Section 3.2 of [1]), we have defined the photon (or the candidate to be registered as the direct photon) as the signal in the 3x3 ECAL crystal cell window satisfying cut conditions (17) – (22) of Section 3.2 of [1]. These cuts effectively discriminate the photons from jets.

In Section 2 it has been shown that even with moderate cuts on P_{tCUT}^{clust} and P_{tCUT}^{out} values the major part of the background events can be suppressed. A wide variation of these two cuts and their influence on the number of events (for $L_{int} = 3 \text{ fb}^{-1}$), and the corresponding values of the signal to background ratio S/B , mean values of vector disbalance $P_t^{\gamma+Jet}$, the mean and the standard deviation values for $(P_t^\gamma - P_t^{Jet})/P_t^\gamma$ variable are presented in Tables 11 – 25 of Appendix. These tables are built after selections (1) – (11) of Table 1 in the beginning of Section 3. The jet in our 1-jet events was found by LUCCELL jetfinder for the whole η region ($|\eta^{Jet}| < 5.0$).

Tables 11 – 15 correspond to the simulation with $\hat{p}_\perp^{min} = 40 \text{ GeV}/c$, Tables 16 – 20 — to $\hat{p}_\perp^{min} = 100 \text{ GeV}/c$ and Tables 21 – 25 — to $\hat{p}_\perp^{min} = 200 \text{ GeV}/c$. The rows and columns of Tables 11 – 25 illustrate the influence of P_{tCUT}^{clust} and P_{tCUT}^{out} cut values on the quantities mentioned above, respectively.

All numbers in Tables 11 – 25 are received with account of the realistic efficiencies of γ^{mes} rejection and electron misidentification as a direct photon.

From Tables 12, 17, 22 and 27, 32, 37 we observe, first of all, noticeable reduction of the background while moving along the diagonal from the right-hand bottom corner to the left-hand upper one, i.e. with reinforcing P_{tCUT}^{clust} and P_{tCUT}^{out} . So, we see that for $\hat{p}_\perp^{min} = 40 \text{ GeV}/c$ the ratio S/B changes in the cells along the diagonal from 3.2, if any limits on these two variables are absent, to 6.5 for $P_{tCUT}^{clust} = 10 \text{ GeV}/c$ and $P_{tCUT}^{out} = 10 \text{ GeV}/c$. Analogously, for $\hat{p}_\perp^{min} = 200 \text{ GeV}/c$ the ratio S/B changes from 12.5 to 48.4 with the same variation of P_{tCUT}^{clust} and P_{tCUT}^{out} .

The second observation. The restriction of P_t^{clust} and P_t^{out} improves the calibration accuracy. Table 14 shows that the mean value of fraction $F \equiv (P_t^\gamma - P_t^{Jet})/P_t^\gamma$ variable decreases from 0.033 (the bottom right-hand corner) to 0.008 for $P_{tCUT}^{clust} = 10 \text{ GeV}/c$ and $P_{tCUT}^{out} = 10 \text{ GeV}/c$. Simultaneously (see Tables 15, 20 and 25 that include the standard deviation values), by this restriction one decreases noticeably (about by twice) the width of the gaussian $\sigma(F)$.

The explanation is simple. The disbalance equation (29) from [1] contains 2 terms in the right-hand side: $(1 - \cos\Delta\phi)$ and $P_t(O+\eta>5)/P_t^\gamma$. The first one is negligibly small

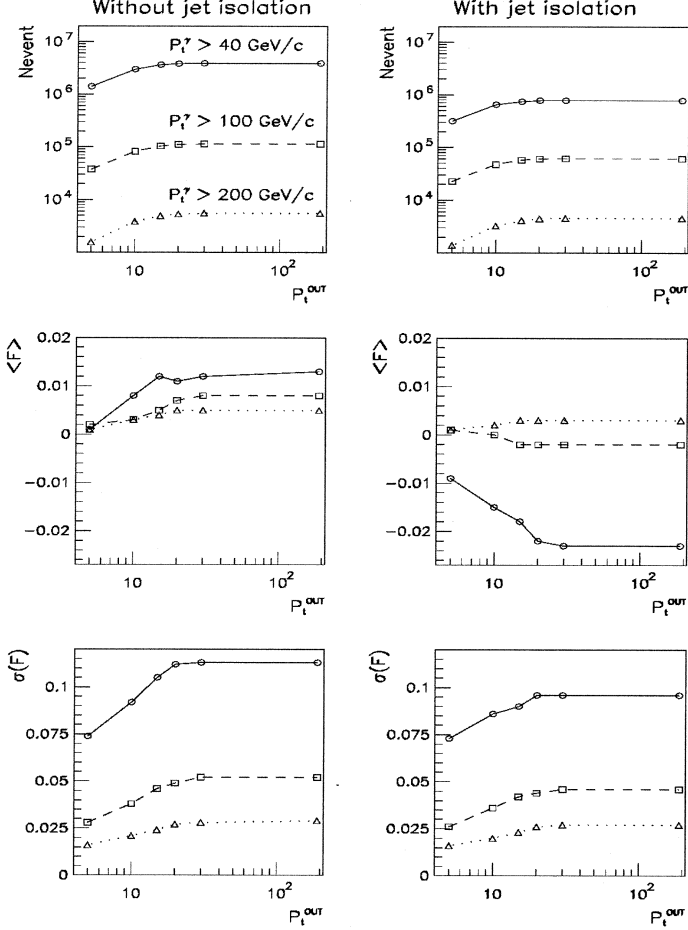

Fig. 8: The distributions of the number of events for $L_{int} = 3 \text{ fb}^{-1}$, the mean value of $(P_t^\gamma - P_t^{Jet})/P_t^\gamma (\equiv \langle F \rangle)$ and its standard deviation $\sigma(F)$ for the cases of nonisolated (left-hand column) and isolated (right-hand column) jet and for three P_t^γ intervals as functions of P_t^{out} value (in GeV/c). $P_{tCUT}^{dust} = 10 \text{ GeV/c}$.

[6, 8] and Barrel [6, 7] ECAL regions. They are of the order of 0.20 – 0.70 for Barrel and 0.51 – 0.75 for Endcap, depending on P_t^γ and a bit on η^γ , for the same single photon selection efficiency 90%. Following [5], for our estimation needs we accept the electron track finding efficiency to be, on the average, equal to 85% for $P_t^e \geq 40 \text{ GeV/c}$, neglecting its η dependence. Then assuming the efficiencies, described above, we have recalculated the numbers in Tables 3–5. They are presented in new Tables 6–8 in the analogy with Tables 3–5 (the background (B) in Tables 6–8 differs from one in Tables 3–5 by including the events with electron candidates with the corresponding efficiencies). Comparing new tables with Tables 3–5 we observe the 50 – 60% growth of S/B ratio for $P_t^\gamma \geq 40 \text{ GeV/c}$ and about the 10% growth for $P_t^\gamma \geq 100 \text{ GeV/c}$.

and tends to decrease more with the growth of P_t^γ (see Tables in Appendices of [3]). So, according to equation (29) of [1], the main source of the disbalance value is $P_t(O+\eta>5)/P_t^\gamma$ term. While decreasing P_t activity out of the jet this term is also decreased and, thus, the calibration accuracy is increased.

The behavior of the number of events for $L_{int} = 3 \text{ fb}^{-1}$, the mean and standard deviation values of the $(P_t^\gamma - P_t^{Jet})/P_t^\gamma$ variable are also displayed in Fig. 8 for isolated and nonisolated jets.

Thus, we can conclude that application of the two criteria introduced in Section 3.2 from [1], i.e. the cuts on the P_t^{clust} and P_t^{out} values, results in two important consequences: significant background reduction and essential improvement of the calibration accuracy.

In Tables 13, 18, 23 the changes of vector disbalance $P_t^{\gamma+Jet}$ with variations of the cuts on the P_t^{clust} and P_t^{out} values are presented. The effect is also evident. The only obvious notice: the value of $P_t^{\gamma+Jet}$ in the upper left-hand corner of these Tables (i.e., when a P_t activity out of the jet region is almost suppressed), becomes approximately equal to the value of $P_t^{\eta>5}$ component (see line “ $P_t^{\eta>5}$ ” in Appendices of [3]).

The numbers of events for different P_{tCUT}^{clust} and P_{tCUT}^{out} values are written in the cells of Tables 11, 16 and 21. One can see that even with such strict P_{tCUT}^{clust} and P_{tCUT}^{out} values as, i.g. $10 \text{ GeV}/c$ for both, we would have a sufficient number of events (3 million, about 80 thousand and 4 thousand for $P_t^\gamma \geq 40 \text{ GeV}/c$, $P_t^\gamma \geq 100 \text{ GeV}/c$ and $P_t^\gamma \geq 200 \text{ GeV}/c$, correspondingly) with low background contamination ($S/B = 6.5, 24.7, 48.4$) as well as good accuracy of the hadron calorimeter calibration during one month of continuous LHC running (i.e. $L_{int} = 3 \text{ fb}^{-1}$)⁶.

In addition, we also present Tables 26-40 for the case of the isolated jet by the complete analogy with Tables 11–25.

4. STUDY OF P_t BALANCE DEPENDENCE ON PARTON k_T .

This Section is dedicated to the study of possible influence of the intrinsic parton transverse momentum on P_t balance of the “ $\gamma + Jet$ ” system. For this aim we consider two different

Table 9: Effect of k_T on $P_t^\gamma - P_t^{Jet}$ balance with $\hat{p}_\perp^{min}=40 \text{ GeV}/c$. $F = (P_t^\gamma - P_t^{Jet})/P_t^\gamma$

$\langle k_T \rangle$ (GeV/c)	ISR is OFF				ISR is ON			
	$\langle P_{t56} \rangle$	$\langle P_t^{5+6} \rangle$	$\langle F \rangle$	$\sigma(F)$	$\langle P_{t56} \rangle$	$\langle P_t^{5+6} \rangle$	$\langle F \rangle$	$\sigma(F)$
0.0	0.0	0.0	-0.002	0.029	8.8	6.9	0.007	0.065

ranges of P_t^γ (or \hat{p}_\perp^{min}): $\hat{p}_\perp^{min} \geq 40 \text{ GeV}/c$ and $\hat{p}_\perp^{min} \geq 200 \text{ GeV}/c$. For these two \hat{p}_\perp^{min} values Tables 9 and 10 demonstrate the average values of P_{t56} and P_t^{5+6} quantities, defined

⁶Nevertheless, only full GEANT simulation would allow to come to a final conclusion.

Fig. 9: $(P_t^\gamma - P_t^{Jet})/P_t^\gamma$ as a function of primordial k_T value for cases of switched on and switched off initial radiation and for $\hat{p}_\perp^{min} = 40$ and $\hat{p}_\perp^{min} = 200$ GeV/c.

Table 10: Effect of k_T on $P_t^\gamma - P_t^{Jet}$ balance with $\hat{p}_\perp^{min} = 200$ GeV/c. $F = (P_t^\gamma - P_t^{Jet})/P_t^\gamma$

$\langle k_T \rangle$ (GeV/c)	ISR is OFF				ISR is ON			
	$\langle P_t^{56} \rangle$	$\langle P_t^{5+6} \rangle$	$\langle F \rangle$	$\sigma(F)$	$\langle P_t^{56} \rangle$	$\langle P_t^{5+6} \rangle$	$\langle F \rangle$	$\sigma(F)$
0.0	0.0	0.0	0.000	0.010	11.1	8.4	-0.001	0.027

7.0	11.2	7.8	0.001	0.029	13.9	10.4	0.002	0.034

* All numbers in the tables above are given in GeV/c units.

by (3) of [1], for two different cases: without including initial state radiation (“ISR is OFF”) and with its account (“ISR is ON”), and various values of parton $\langle k_T \rangle$: from its absence ($\langle k_T \rangle = 0$) up to $\langle k_T \rangle = 7$ GeV/c. The numbers in Tables 9 and 10 (obtained from the events set chosen by the following cuts: $\Delta\phi < 15^\circ$, $P_{tCUT}^{out} = 5$ GeV/c and $P_{tCUT}^{clust} = 10$ GeV/c) have shown that the values of $\langle P_t^{56} \rangle$ and $\langle P_t^{5+6} \rangle$ grow rapidly with $\langle k_T \rangle$ increasing if ISR is absent, in fact, with the values of $\langle k_T \rangle$. The picture changes when ISR is included. In this case the disbalance values become large already in the case of $\langle k_T \rangle = 0$: $\langle P_t^{56} \rangle = 8.8$ GeV/c at $\hat{p}_\perp^{min} = 40$ GeV/c and $\langle P_t^{5+6} \rangle = 11.1$ GeV/c at $\hat{p}_\perp^{min} = 200$ GeV/c. The values of $\langle P_t^{56} \rangle$ and $\langle P_t^{5+6} \rangle$ grow very slowly from their initial values at $\langle k_T \rangle = 0$ by 2 – 3 GeV/c showing their practical independence on $\langle k_T \rangle$ in the range of its reasonable value $\langle k_T \rangle \leq 1$ GeV/c.

The size of relative disbalance $F = (P_t^\gamma - P_t^{Jet})/P_t^\gamma$ variation with k_T is also shown in Tables 9 and 10 and in plots of Fig. 9. One can see that for reasonable values $\langle k_T \rangle \leq 1$ GeV/c it is quite small.

APPENDIX

$$\hat{p}_{\perp}^{min} = 40 \text{ GeV}/c.$$

5. ACKNOWLEDGMENTS

We are greatly thankful to D. Denegri for having offered this theme to study, fruitful discussions and permanent support and encouragement. It is a pleasure for us to express our recognition for helpful discussions to P. Aurenche, M. Dittmar, M.L. Mangano, H. Rohringer, S. Taprogge, M. Fontannaz, J.Ph. Guillet, E. Pilon and J. Womersley.

Установка шкалы энергии струи
с использованием « $\gamma+Jet$ » событий при энергиях LHC.
Детальное изучение подавления фона

E2-2000-255

Проводится детальное изучение возможностей подавления фоновых событий, основанных на КХД-процессах qg -, gg -, qq -рассеяний с большим поперечным сечением. На основе введенных критериев отбора определяются коэффициенты подавления фоновых и эффективности отбора сигнальных событий, а также число событий, которые могут быть собраны на LHC при низкой светимости $L=10^{33} \text{ см}^2 \cdot \text{с}^{-1}$ в течение одного месяца непрерывной работы.

Работа выполнена в Лаборатории ядерных проблем им. В.П.Джелепова ОИЯИ.

Detailed Study of the Background Suppression

E2-2000-255

The possibilities of the background events suppression, based on the QCD subprocesses of qg -, gg -, qq -scattering with big cross sections, to the signal « $\gamma+Jet$ » events are studied. Basing on the introduced selection criteria, the background suppression factors and signal events selection efficiencies and the number of the events, that can be collected at LHC with low luminosity $L=10^{33} \text{ cm}^2 \cdot \text{s}^{-1}$ during one month of continuous work, are determined.

The investigation has been performed at the Dzhelapov Laboratory of Nuclear Problems, JINR.
